Right-hand rule

The vector product $\vec{A} \times \vec{B}$ determined by the right-hand rule.

$$\vec{B} \times \vec{A} = -\vec{A} \times \vec{B}$$

- ① Place \vec{A} and \vec{B} tail to tail.
- ② Point fingers of right hand along \vec{A} , with palm facing \vec{B} .
- ③ Curl fingers toward \vec{B} .
- ④ Thumb points in direction of $\vec{A} \times \vec{B}$.

Hall voltage

http://courses.washington.edu/phys431/hall_effect/hall_effect.pdf

Assume the conductor to have charge carrier of charge q (can be either positive or negative or both, but we take it to be of just one sign here), charge carrier number density n (i.e., number of carriers per unit volume), and charge carrier drift velocity v_x when a current I_x flows in the positive x direction.

Hall voltage

The charge carriers will experience a Lorentz force $q(\mathbf{v} \times \mathbf{B})$ that will deflect them toward one side of the slab. The result of this deflection is to cause an accumulation of charges along one side of the slab which creates a transverse electric field E_y that counteracts the force of the magnetic field.

http://courses.washington.edu/phys431/hall_effect/hall_effect.pdf

Hall voltage

http://courses.washington.edu/phys431/hall_effect/hall_effect.pdf

When steady state is reached, there will be no net flow of charge in the y direction, since the electrical and magnetic forces on the charge carriers in that direction must be balanced. Since the force of an electric field on a charge q is $q\mathbf{E}$, we have

$$q\mathbf{E} = q(\mathbf{v} \times \mathbf{B})$$

$$E_y = v_x B_z$$

Hall voltage

http://courses.washington.edu/phys431/hall_effect/hall_effect.pdf

The potential difference across the sample — the Hall voltage V_H — which is related to the Hall field by

$$\begin{aligned} V_H &= -E_y w \\ &= -v_x w B_z \end{aligned}$$

The current I_x is related to the charge density nq and the drift velocity v_x as

$$I_x = nq v_x w t$$

Hall voltage

http://courses.washington.edu/phys431/hall_effect/hall_effect.pdf

$$V_H = - \left(\frac{1}{nq} \right) \frac{I_x B_z}{t}$$

$$\text{The Hall coefficient: } R_H = \frac{1}{nq}$$

It is positive if the charge carriers are positive, and negative if the charge carriers are negative. In practice, the polarity of V_H determines the sign of the charge carriers.

Assignments

- Discuss how the Hall effect could be used to obtain information on free charge density in a conductor. (Hint: Consider how drift velocity and current are related.)
- Can mobility of charge carriers can be determined from Hall effect? If yes, how?
